ACKNOWLEDGEMENTS

The Business Community Outreach and Incentives Division's (BCOID) Aquifer Sampling and Assessment (ASSET) Program owes its success to many people and agencies for their continual support through the years. Without this support, the ASSET Program could not exist.

The water well owners, who voluntarily participate in ASSET, are owed a debt of gratitude. Without access to private, corporate, and public property and wellheads, this program could not operate.

The Louisiana Department of Natural Resources (LDNR) Ground Water Resources Program makes the Water Well Registration data set available to LDEQ, and ultimately to the BCOID, which is used for multiple purposes in the execution of ASSET.

The United States Geological Survey (USGS) Water Resources Division frequently provides well schedule data that are used during the execution of ASSET. These data are made available to the Program through a USGS-LDOTD cooperative program. In addition, the USGS allows its observation wells to be sampled.

Gratitude is also owed to the staff at EPA Region 6, Water Quality Protection Division, Assistance Programs Branch and the Source Water Protection Branch, for their assistance and support for ASSET.

This Program is funded in part by the U.S. Environmental Protection Agency through the Clean Water Act.

BACKGROUND

The Aquifer Sampling and Assessment Program, or ASSET, is conducted as a Clean Water Act activity. ASSET was designed to determine and monitor the quality of groundwater in the major freshwater aquifers across Louisiana. The data derived from this process is provided to LDEQ to aid in groundwater protection through nonpoint source pollution prevention, source water protection and remediation strategies for the State. It is also available to the public through LDEQ's website, email, and through the mail upon request. Also, each well owner receives a copy of the laboratory analytical results from the sampling of their well.

For this reporting period, the ASSET Program monitored 191 wells in fourteen major freshwater aquifers throughout the state. Table 2 illustrates their stratigraphic occurrence while Table 3 lists these major aquifers. The number of wells assigned to each aquifer is based on its areal extent. Currently, the well density goal is approximately one well per 400 square miles. For example, an aquifer with an areal extent of 4,800 square miles would require a minimum of 12 wells to be assigned to it, $4,800/400 = 12$. An effort is made to distribute sample locations (wells) evenly within the areal extent of each aquifer so that a representative sampling of the aquifer can be accomplished. Table 3 lists the square miles of each aquifer, the number of wells currently assigned to it and the well density for each aquifer. Figures 1 - 3 more readily illustrates this by graphing the data found in Table 3. Also, the last row of Table 3 lists the total areal extent of all monitored aquifers, total number of wells sampled and the overall well density for the Program.

The sampling process was designed so that each well is monitored every three years. Following this design allows for all fourteen aquifers to be monitored within the three-year period. The process is then repeated once a three-year cycle has been completed. Typically, five or more wells, each producing from the same aquifer, are sampled each time sampling is performed. An effort is made to sample all assigned wells of the aquifer in question within a consecutive set of sampling events before moving to the next aquifer. Aquifers of small areal extent may have been completed in a single event, whereas larger aquifers may have required several events to complete. Table 4 lists the sample schedule by aquifer along with the month and number of wells sampled.

Each well is sampled for water quality parameters, inorganics (total metals), nutrients, volatile organic compounds, semi-volatile organic compounds, pesticides, and PCBs; and field parameters (temperature, pH, specific conductance, total dissolved solids, and salinity) are measured and recorded at each well. Table 8 lists these field and laboratory parameters along with their reporting units. For specific lists of analytes, methods, and detection limits, please refer to the aquifer summaries appended to this document.

SUMMARY OF FINDINGS

INTRODUCTION

This report summarizes ASSET sampling that occurred from July 2009 through June 2012. One hundred ninety-one wells completed in fourteen different aquifers were monitored. Table 9 contains a listing of all the wells sampled, each well's owner, completed depth, use made of produced water, and the aquifers they produce from. In order to preserve privacy, "Private Owner" is listed for the well owner when a well is owned by a private citizen.

Table 5 lists the minimum, average and maximum sample results for the samples collected from each aquifer for field and conventional parameters. Table 6 lists the minimum, average and maximum sample results for the samples collected from each aquifer for inorganic parameters.

A brief summation of each aquifer's sample results and conclusions begins on the next page. Each summation includes the findings for hardness based on the scale below, and a statement on the general water quality of the aquifer based on the data derived from the wells sampled. The number of federal primary Maximum Contaminant Levels (MCLs), if any, and the number of secondary MCL's (SMCLs) that were exceeded are noted also.

For a detailed discussion of each aquifer's findings, see the aquifer summaries appended to this document. Each summary consists of a discussion of the aquifer's geology and hydrogeology, and an interpretation of the laboratory analyses. The lab analysis interpretation is accomplished by evaluating the general water quality and by comparing the historical data averages with the current data averages to detect changes in water quality over time. Initial water quality is evaluated by comparing individual parameters to their respective MCLs to assess the aquifer's use as a drinking water source, and is rated as good (no MCL exceedances), fair (no MCL exceedances in a drinking water well) or poor (one or more MCL exceedance in a drinking water well). Additionally a second water quality evaluation is made by taking into account whether or not Action Levels were exceeded, whether or not volatile organic compounds, semi-volatile organic compounds, pesticides or PCBs were detected, the number of SMCLs exceeded in relation to the number of wells sampled, and the average hardness value. This rating uses values of good, fair and poor.

It should be noted that all statements about hardness (as CaCO₃) in the aquifer sections and summary section are based on the following scale¹:

Soft	< 50 milligrams per Liter (mg/L)
Moderately hard	50-150 mg/L
Hard	151-300 mg/L
Very hard	> 300 mg/L

A statewide summary of findings and summary statement can be found in the section following the Aquifer Summations section.

¹ Classification based on hardness scale from: Peavy, H. S. et al. *Environmental Engineering*. New York: McGraw-Hill, 1985.

AQUIFER SUMMATIONS

Sparta Aquifer

Fourteen wells ranging in depth from 153 feet to 773 feet, with an average depth of 523 feet were sampled for this aquifer. Laboratory and field data show that of these 14 wells sampled during this reporting period for the Sparta aquifer, no primary MCL was exceeded, while 25 secondary standards were exceeded. The data also show that the groundwater produced from this aquifer is soft, and is of good quality when considering short-term or long-term health risk guidelines. Water produced from this aquifer is of fair quality when considering taste, odor, or appearance guidelines.

Carrizo-Wilcox Aquifer

Twelve wells ranging in depth from 105 feet to 410 feet, with an average depth of 258 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Carrizo-Wilcox aquifer exceeded a primary MCL, with 18 exceedances of secondary standards. The data show that the groundwater produced from this aquifer is generally soft, and is of good quality when considering short-term or long-term health risk guidelines. Water produced from this aquifer is also of good quality when considering taste, odor, or appearance guidelines.

Red River Alluvial Aquifer

Five wells ranging in depth from 58 feet to 89 feet, with an average depth of 73 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Red River Alluvial aquifer exceeded a primary MCL, while nine secondary standards were exceeded. The data also show that the groundwater produced from this aquifer is very hard and is of poor quality when considering taste, odor, or appearance guidelines, but is of good quality when considering short-term or long-term health risk guidelines.

Evangeline Aquifer

Twelve wells ranging in depth from 170 feet to 1,715 feet, with an average depth of 635 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Evangeline aquifer exceeded a primary MCL, while there were six exceedances of secondary standards. The data show that the groundwater produced from this aquifer is generally soft, and is of good quality when considering short-term or long-term health risk guidelines. Water produced from this aquifer is also of good quality when considering taste, odor, or appearance guidelines.

Catahoula Aquifer

Five wells ranging in depth from 352 feet to 910 feet, with an average depth of 678 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Catahoula aquifer exceeded a primary MCL, and only one secondary standard was exceeded. The data show that the groundwater produced from this aquifer is soft, and is of good quality when considering short or long-term health risk guidelines. Also, the water produced from this aquifer is of good quality when considering taste, odor, or appearance guidelines.

North Louisiana Terrace Aquifer

Eleven wells ranging in depth from 49 feet to 158 feet, with an average depth of 107 feet were sampled for this aquifer. Laboratory and field data show that the groundwater produced from this aquifer is moderately hard and is of fair to good quality when considering taste, odor, or appearance guidelines, with 15 secondary standards exceeded. It is also of good quality when considering short-term or long-term health risk guidelines in that no well sampled for this time period exceeded a primary MCL.

Carnahan Bayou Aquifer

Ten wells ranging in depth from 66 feet to 2,036 feet, with an average depth of 801 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Carnahan Bayou aquifer exceeded a primary MCL, and only five secondary standards were exceeded. The data show that the groundwater produced from this aquifer is soft except for the extreme eastern portion of the aquifer that is moderately hard. Data also show that it is of good quality when considering short or long-term health risk guidelines, and is of good quality when considering taste, odor, or appearance guidelines.

Mississippi River Alluvial Aquifer

Twenty-three wells ranging in depth from 30 feet to 352 feet, with an average depth of 129 feet were sampled for this aquifer. Laboratory and field data show that the groundwater produced from the Mississippi River Alluvial aquifer is hard, and that the primary MCL for arsenic was exceeded in five of the 23 wells sampled.

Review of this data shows that this aquifer is of poor quality when considering taste, odor, or appearance guidelines, with 33 secondary standards being exceeded. It also shows that five wells exceeded the MCL for arsenic, making certain locations of this aquifer to be of poor quality when considering short-term or long-term health risk guidelines. It is important to note that there are certain localized areas of the Mississippi River Alluvial aquifer that exhibit good water quality characteristics, but it still exhibits the poorest overall water quality characteristics of any of the fourteen aquifers or aquifer systems sampled.

Cockfield Aquifer

Fourteen wells ranging in depth from 80 feet to 445 feet, with an average depth of 246 feet were sampled for this aquifer. Laboratory and field data show that the groundwater produced from this aquifer is of good quality when considering short or long-term health risk guidelines. The data also show that this aquifer is moderately hard and is of poor quality when considering taste, odor, or appearance guidelines, with 21 secondary standards exceeded in 13 of the 14 wells sampled.

Chicot Aquifer

Twenty-three wells ranging in depth from 66 feet to 697 feet, with an average depth of 335 feet were sampled for this aquifer. Laboratory and field data show that no assigned well sampled during this reporting period for the Chicot aquifer exceeded a primary MCL, while 35 SMCLs were exceeded. These findings show that the water produced from the Chicot aquifer is of good quality when considering short-term or long-term health risk guidelines. The data also show that the water produced from the Chicot aquifer is hard and is of poor quality when considering taste, odor, or appearance guidelines.

Williamson Creek Aquifer

Seven wells ranging in depth from 190 feet to 1,657 feet, with an average depth of 628 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during

this reporting period for the Williamson Creek aquifer exceeded a primary MCL and only three secondary standards were exceeded. Review of the data shows that the water produced from the Williamson Creek aquifer is soft, is of good quality when considering short-term or long-term health risk guidelines, and is also of good quality when considering taste, odor, or appearance guidelines.

Chicot Equivalent Aquifer System

Twenty-five wells ranging in depth from 90 feet to 775 feet, with an average depth of 342 feet were sampled for this aquifer. Laboratory and field data show that the groundwater produced from this aquifer is moderately hard and is of good quality when considering short-term or long-term health risk guidelines. The data also show that this aquifer is of fair quality when considering taste, odor, or appearance guidelines, with 26 secondary standards exceeded in 16 wells.

Evangeline Equivalent Aquifer System

Sixteen wells ranging in depth from 185 feet to 2,004 feet, with an average depth of 963 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Evangeline Equivalent Aquifer System exceeded a primary MCL, whereas 16 secondary standards were exceeded. The data show that the water produced from the Evangeline Equivalent aquifer system is soft and of good quality when considering short-term or long-term health risk guidelines, and is also of good quality when considering taste, odor, or appearance guidelines.

Jasper Equivalent Aquifer System

Fifteen wells ranging in depth from 960 feet to 2,700 feet, with an average depth of 2,025 feet were sampled for this aquifer. Laboratory and field data show that no assigned well that was sampled during this reporting period for the Jasper Equivalent Aquifer System exceeded a primary MCL, while 11 secondary standards were exceeded. The data also show that the water produced from the Jasper Equivalent aquifer system is soft and of good quality when considering short-term or long-term health risk guidelines, and is of good quality when considering taste, odor, or appearance guidelines.

STATEWIDE SUMMARY OF FINDINGS

COMBINED AQUIFER DATA AND HISTORICAL COMPARISON

Table 7 shows the minimum and maximum sample results from the fourteen aquifers and aquifer systems that were sampled for field parameters, conventional parameters (water quality and nutrients), and inorganics (total metals), as well as an average of all these sample results. A comparison of the current average values of each parameter to the historical average values of the four previous reporting periods ([2000, 2003, 2006, and 2009 Triennial Summary Reports](#)) shows that there was little or no change for the majority of the parameters measured. Of the thirty-two parameters compared, only four exhibited notable changes in average values. The statewide average for pH exhibited a slight but consistent increase of about one half a Standard pH Unit (0.5 SU) from 2000 to 2012 and the statewide chloride average increased by approximately 10 mg/L. The statewide average for color decreased by about 2 PCU's and the statewide average for copper decreased by approximately 30 µg/L during this time period. However, this decrease in copper may be related to the condition of wells sampled rather than an actual decrease in copper concentrations.

Table 1 highlights the minimum, maximum, and average statewide values for pH, TDS, hardness, chloride, iron, and nitrite-nitrate found in Table 7. The only statewide average listed in Table 1 that did not meet federal drinking water standards is the average for iron, which is not a health-related primary standard, but an aesthetic, non-enforceable, secondary standard. Figures 4 – 9 are the graphed representations of the average values for these same parameters on an aquifer by aquifer basis for this reporting period, July 2009 – June 2010.

Figures 10 – 29 are the graphed representations of selected analytes resulting from the statewide average for each analyte for each three year period from 2000 to 2012. Some are presented in logarithmic scale to more readily show the relationship between the graphed values and the various limits associated with the analyte.

FEDERAL PRIMARY MCL EXCEEDANCES

A review of the laboratory and field data from all the aquifers and aquifer systems sampled show that there were five exceedances of the primary MCL for arsenic, all in the Mississippi River Alluvial aquifer. For further discussion of the occurrence of arsenic in the Mississippi River Alluvial aquifer, please see Appendix 8 – Mississippi River Alluvial Aquifer Summary.

QUALITY RANKINGS

As stated previously, initial water quality is evaluated by comparing individual parameters to primary MCLs to assess the aquifer's use as a drinking water source, and is rated as good (no MCL exceedances), fair (no MCL exceedances in a drinking water well), or poor (one or more MCL exceedance in a drinking water well). Additionally a second water quality evaluation is made by taking into account whether or not Action Levels were exceeded, whether or not volatile organic compounds, semi-volatile organic compounds, pesticides or PCBs were detected, the number of secondary standards exceeded in relation to the number of wells sampled, and the average hardness value. This rating uses values of good, fair and poor.

Using the above stated criteria against the data derived from the FY10 – FY12 sampling time period it was determined, based on initial evaluation, that 13 of the 14 aquifers and aquifer systems monitored exhibit good water quality characteristics while one exhibited poor water quality characteristics.

Secondary evaluation shows that seven are in the good range; three are in the fair range and four are considered to be poor.

Those aquifers and aquifer systems considered by the ASSET Program to have Good water quality characteristics in both categories are: Carrizo-Wilcox, Carnahan Bayou, Catahoula, Evangeline, Evangeline Equivalent, Jasper Equivalent, and Williamson Creek. The Chicot Equivalent, Sparta, and North Louisiana Terrace aquifers are considered to have Good water quality in the initial category and Fair water quality in the second category. Aquifers considered having Good initial water quality with Poor secondary water quality characteristics are the Chicot, Cockfield, and Red River Alluvial aquifers. The Mississippi River Alluvial aquifer is considered to have Poor initial and secondary water quality characteristics by this Program.

SUMMARY STATEMENT

The majority of the major freshwater aquifers of Louisiana that were sampled by the ASSET Program exhibited Good water quality characteristics when considering health based standards and Fair to Good water quality characteristics when considering non-health based standards. Half of the aquifers sampled exhibited Good water quality characteristics in both categories, while only the Mississippi River Alluvial aquifer exhibited Poor water quality characteristics in both categories.

Those aquifers with deeper average well depths typically exhibit the best water quality characteristics while those with shallower average well depths exhibit some of the poorest water quality characteristics. One notable exception to this is the North Louisiana Terrace aquifer that has an average well depth of just over 100 feet and exhibits similar water quality characteristics to those aquifers with much deeper average well depths.

Taking into account short-term and long-term health risk guidelines, along with the findings of the Aquifer Sampling and Assessment Program for the Fiscal Years 2000 to 2012, it is determined that the overall quality of the waters produced from Louisiana’s principal freshwater aquifers is good, and that there is very little change in the water quality characteristics of these aquifers.
